Inference on Sports with Beta-Binomial Model

Andrew White

November 24, 2013

1 Model

We're going to use a beta-binomial. The data will be a matrix of wins x_{ij} and a matrix of total games played between opponent i and j, n_{ij} . The probability of a win is p_{ij} which comes from a beta distribution with parameters (α_i, α_j) . The α s are the team strengths, and are in units of psuedo-wins.

To generate samples from this model given a schedule, first sample the probability that team i beats team j (p_{ij}) from $\text{Beta}(\alpha_i, \alpha_j)$. Next, sample an outcome of the game given p_{ij} .

To sample parameters for this model, we'll use Markov Chain Monte Carlo . First, we sample each individual p_{ij} . Those are independent and distriubted according:

$$\Pr(p_{ij}|X, N, \vec{\alpha}) = \frac{\Gamma(\alpha_i + x_{ij}, \alpha_j + n_{ij} - x_{ij})}{\Gamma(\alpha_i + x_{ij})\Gamma(\alpha_i + n_{ij} - x_{ij})} p_{ij}^{x_{ij} + \alpha_i - 1} (1 - p_{ij})^{n_{ij} - x_{ij} + \alpha_j - 1}$$

Then we use a Metropolis-hastings move for the α vector. Stochastically, we choose an index k and then randomly perturb α_k until all of them have been sampled. The likelihood ratio is evaluated as:

$$\Pr(\vec{\alpha}|...) = \prod_{\substack{n_i \in i > j \\ \Gamma(\alpha_i) \Gamma(\alpha_j)}} \frac{\Gamma(\alpha_i + \alpha_j)}{\Gamma(\alpha_i)\Gamma(\alpha_j)} p_{ij}^{\alpha_i - 1} (1 - p_{ij})^{\alpha_j - 1}$$

$$\frac{\Pr(\alpha'_k|...)}{\Pr(\alpha_k|...)} = \left[\prod_{p_{kj} \in j > k} \frac{\Gamma(\alpha'_k + \alpha_j)\Gamma(\alpha_k)}{\Gamma(\alpha_k + \alpha_j)\Gamma(\alpha'_k)} p_{kj}^{\alpha'_k - \alpha_k} \right] \cdot \left[\prod_{p_{ik} \in k > i} \frac{\Gamma(\alpha'_k + \alpha_i)\Gamma(\alpha_k)}{\Gamma(\alpha_k + \alpha_i)\Gamma(\alpha'_k)} (1 - p_{ik})^{\alpha'_k - \alpha_k} \right]$$

```
\begin{array}{l} \mathbf{Data} \colon X \text{ (times team $i$ beat team $j$), $N$ (games played between $i$ and $j$), $$ $m$ (number of teams) \\ \mathbf{Result} \colon \vec{\alpha} \\ \mathbf{Initialize} \colon \alpha_i = \sum_j x_{ij}, \, p_{ij} = 0.5; \\ \mathbf{while} \ True \ \mathbf{do} \\ & | \ \mathbf{for} \ i \ in \ 0 \dots m-1 \ \mathbf{do} \\ & | \ \mathbf{for} \ j \ in \ i+1 \dots m-1 \ \mathbf{do} \\ & | \ \mathbf{Sample} \ p_{ij} \ \mathbf{from} \ \mathbf{Beta}(\alpha_i + x_{ij}, \alpha_j + n_{ij} - x_{ij}) \ \mathbf{Set} \ p_{ji} = 1 - p_{ij}; \\ & | \ \mathbf{end} \\ & \mathbf{end} \\ & \mathbf{for} \ sample \ \epsilon \ \mathbf{uniformly} \ \mathbf{from} \ [-\eta, \eta]; \\ & | \ \mathbf{propose} \ \alpha_k' = \alpha_k + \epsilon; \\ & | \ \mathbf{Accept} \ \mathbf{with} \ \mathbf{probability} \ \mathbf{min} \ \left( \frac{\Pr(\alpha_k'|\dots)}{\Pr(\alpha_k|\dots)}, 1 \right) \ (\mathbf{Eq.} \ 1); \\ & \mathbf{end} \\ & | \ \mathbf{Histogram} \ \vec{\alpha}; \\ & \mathbf{end} \\ & | \ \mathbf{end} \end{array} \right.
```

Algorithm 1: Sampling parameters for the model

```
Data: N (games played between i and j), \vec{\alpha}, m (number of teams)

Result: X (the win matrix), f(X) (a function of the result of the games)

while True do

Initialize X = 0;

for i in 0 \dots m - 1 do

for j in i + 1 \dots m - 1 do

Sample p_{ij} from Beta(\alpha_i, \alpha_j);

Sample x_{ij} from Bin(p_{ij}, n_{ij});

Set x_{ji} = n_{ij} - x_{ij};

end

end

Histogram X and/or f(X);
```

Algorithm 2: Generating realizaions of the win matrix from the model

2 Algorithm

3 Logrithm Transformations

3.1 Equation 2

$$\ln\left(\frac{\Pr(\alpha'_k|\dots)}{\Pr(\alpha_k|\dots)}\right) = \sum_{p_{kj} \in j > k} \ln\Gamma(\alpha'_k + \alpha_j) + \ln\Gamma(\alpha_k) + (\alpha'_k - \alpha_k) \ln p_{kj} - \ln\Gamma(\alpha_k + \alpha_j) - \ln\Gamma(\alpha'_k) + \sum_{p_{ik} \in k > i} \ln\Gamma(\alpha'_k + \alpha_i) + \ln\Gamma(\alpha_k) + (\alpha'_k - \alpha_k) \ln(1 - p_{ik}) - \ln\Gamma(\alpha'_k + \alpha_i) - \ln\Gamma(\alpha'_k)$$

$$(2)$$

4 Stirling's Approximation

$$\frac{\Gamma(x+\alpha)}{\Gamma(x+\beta)} \approx x^{\beta-\alpha}$$

$$\ln\left(\frac{\Gamma(x+\alpha)}{\Gamma(x+\beta)}\right) \approx (\beta-\alpha)\ln x$$

$$\ln\left(\frac{\Gamma(\alpha)}{\Gamma(\beta)}\right) \approx (\alpha-0.5)\ln \alpha - (\beta-0.5)\ln \beta + (\beta-\alpha)$$

$$\approx \alpha(\ln \alpha - 1) - \beta(\ln \beta - 1)$$

$$\ln\left(\frac{\Pr(\alpha_k'|\dots)}{\Pr(\alpha_k|\dots)}\right) \approx \sum_{p_{kj} \in j > k} (\alpha_k' - \alpha_k) \left[\ln(\alpha_j) + \ln p_{kj}\right] + \alpha_k (\ln \alpha_k - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' - 1) + \alpha_k (\ln \alpha_k' - 1) - \alpha_k' (\ln \alpha_k' -$$

$$\sum_{p_{ik} \in k > i} (\alpha'_k - \alpha_k) \left[\ln(\alpha_i) + \ln(1 - p_{ik}) \right] + \alpha_k (\ln \alpha_k - 1) - \alpha'_k (\ln \alpha'_k - 1)$$
